DESCRIPTION

EXHAUST PURIFICATION DEVICE OF INTERNAL COMBUSTION ENGINE

5   TECHNICAL FIELD

The present invention relates to an exhaust purification device of an internal combustion engine.

BACKGROUND ART

As a catalyst for purifying NO_x contained in exhaust
10   gas when fuel is burned under a lean air-fuel ratio,
there is known a catalyst comprised of a carrier made of alumina on the surface of which a layer of a NO_x absorbent comprised of an alkali metal or alkali earth is formed and on that surface of which a precious metal catalyst
15   such as platinum is carried (for example, see Japanese Patent No. 2600492). In this catalyst, when the air-fuel ratio of the exhaust gas is lean, the NO_x contained in the exhaust gas is oxidized by the platinum and absorbed in the NO_x absorbent in the form of a nitrate. Next, when the
20   air-fuel ratio of the exhaust gas is made rich in a short time, the NO_x which had been absorbed in the NO_x absorbent during that time is released and reduced. Next, when the air-fuel ratio of the exhaust gas returns to lean, the action of absorption of the NO_x in the NO_x absorbent is
25   started.

On the other hand, exhaust gas also contains SO_x. The NO_x absorbent absorbs the SO_x in addition to the NO_x. In this case, the SO_x is absorbed in the form of a sulfate. However, this sulfate is harder to break down compared
30   with a nitrate and will not break down if simply making the air-fuel ratio of the exhaust gas rich. Therefore, the NO_x absorbent gradually increases in the amount of absorption of the SO_x. Along with this, it can no longer absorb NO_x. Therefore, when using such a NO_x absorbent, it
35   is necessary to make it release the SO_x. In this regard, a sulfate becomes easy to break down when the temperature of the catalyst becomes 600°C or more. If making the air-

fuel ratio of the exhaust gas rich at this time, the SO_x is released from the NO_x absorbent. Accordingly, if using such a NO_x absorbent, when making the NO_x absorbent release the SO_x, the temperature of the catalyst is maintained at 600°C or more and the air-fuel ratio of the exhaust gas is maintained rich.

Further, if providing a layer of such a NO_x absorbent, SO_x is inevitably also absorbed in addition to the NO_x, so to prevent the SO_x from being absorbed, it would be sufficient not to provide such a layer of a NO_x absorbent. Therefore, a catalyst comprised of a carrier made of alumina on which only platinum is carried has been proposed (see Japanese Unexamined Patent Publication (Kokai) No. 11-285624). This publication describes that NO_x can be purified even when a carrier made of alumina carries only platinum if trapping NO_x in the catalyst when the air-fuel ratio is lean and switching the air-fuel ratio alternately between lean and rich.

Further, as a catalyst able to purify the NO_x generated when fuel is burned under a lean air-fuel ratio, a lean NO_x catalyst comprised of zeolite carrying a transition metal or precious metal is known. This lean NO_x catalyst has the function of absorbing the HC and NO_x in the exhaust gas and reducing the NO_x, but if oxygen is adsorbed, the NO_x purification performance remarkably drops. Therefore, an internal combustion engine designed to cause the adsorbed oxygen to disassociate by periodically making the air-fuel ratio of the exhaust gas flowing into a lean NO_x catalyst rich is known (see Japanese Patent No. 3154110). This lean NO_x catalyst has the feature of being able to reduce NO_x even when fuel is burned under a lean air-fuel ratio, but has the defects that the exhaust gas has to be supplied with HC for reducing the NO_x, the heat resistance is low, and a purification rate of only 50 percent or less can be obtained.

The inventors researched catalysts comprised of a

carrier formed with a layer of a NO_x absorbent, but also
researched catalysts comprised of a carrier not having a
layer of a NO_x absorbent. As a result, they learned that
with a catalyst comprised of carrier not having a layer

5   of a NO_x absorbent, for example, a catalyst comprised of a
carrier made of alumina on which only platinum is
carried, if temporarily making the air-fuel ratio rich
when burning fuel under a lean air-fuel ratio, a NO_x
purification rate of 90 percent or more can be obtained

10   when the catalyst temperature is a low temperature of
250°C or less.

       The inventors engaged in repeated studies on the
reasons for this from various angles and as a result
reached the following conclusion. That is, generally

15   speaking, platinum inherently has activity at a low
temperature. The NO_x contained in exhaust gas is directly
broken down or selectively reduced on the surface of the
platinum. Further, a carrier made of alumina has base
points on its surface. NO_x oxidized on the surface of the

20   platinum is adsorbed on the surface of the carrier in the
form of NO_2 or is held on the base points on the surface
of the carrier in the form of nitrate ions NO_3^-. When
purifying the NO_x, these various actions are performed
simultaneously. As a result, a high purification rate of

25   90 percent or more is obtained.

       However, if exposing a catalyst comprised of a
carrier made of alumina on which only platinum is carried
to exhaust gas of a lean air-fuel ratio, the NO_x
purification rate gradually falls. This is because the

30   surface of the platinum is covered by oxygen atoms, that
is, the surface of the platinum suffers from oxygen
poisoning, whereby the direct breakdown of NO_x or
selective reduction of NO_x on the platinum surface becomes
difficult. In practice, if making the air-fuel ratio

35   temporarily rich at this time, the oxygen atoms covering
the platinum surface will be consumed for oxidation of
the HC or CO, that is, the oxygen poisoning of the

platinum surface will be eliminated. When the air-fuel ratio returns to lean next, the direct breakdown of NO_x or selective reduction of NO_x will again be performed well.

On the other hand, if the surface of the platinum is covered by oxygen atoms, the NO_x will become more easily oxidized on the surface of the platinum and therefore the amount of the NO_x adsorbed or held on the carrier will increase. Regardless of this, the fall in the NO_x purification rate means that the direct breakdown of NO_x or selective reduction of NO_x governs the purification action of NO_x. Therefore, when carrying only platinum on a carrier made of alumina, preventing the entire surface of the platinum from becoming poisoned by oxygen is the most important issue. Therefore, it becomes necessary to temporarily switch the air-fuel ratio of the exhaust gas from lean to rich before the entire surface of the platinum suffers from oxygen poisoning.

Note that if temporarily switching the air-fuel ratio of the exhaust gas from lean to rich, the NO_x adsorbed on the carrier or the nitrate ions NO_3^- held on the carrier is reduced by the HC and CO. That is, if temporarily switching the air-fuel ratio of the exhaust gas from lean to rich to eliminate the oxygen poisoning of the surface of the platinum, the NO_x adsorbed or held on the carrier is removed. Therefore, when the air-fuel ratio is returned from rich to lean, the action of adsorption of NO_x or the action of holding the nitrate ions NO_3^- is started.

As explained above, when carrying only platinum on a carrier made of alumina, to secure a high purification rate of NO_x, it is necessary to prevent the entire surface of the platinum from becoming poisoned by oxygen. However, neither Japanese Unexamined Patent Publication (Kokai) No. 11-285624 nor Japanese Patent No. 3154110 suggests anything regarding this. That is, Japanese Unexamined Patent Publication (Kokai) No. 11-285624 shows the results of studies all predicated on NO_x being

purified based on the action of adsorption of NO_x. It does not notice that oxygen poisoning of platinum governs the purification rate of NO_x. Accordingly, only naturally, Japanese Unexamined Patent Publication (Kokai) No. 11-285624 does not suggest anything regarding obtaining a high purification rate even with a low temperature of 250°C or less.

Further, Japanese Patent No. 3154110 covers a lean NO_x catalyst comprised of zeolite and discloses that the adsorption of oxygen at this lean NO_x catalyst has an effect on the NO_x purification rate, but does not suggest anything regarding the fact that oxygen poisoning of the surface of platinum governs the NO_x purification rate. This zeolite has no base points, so not only does the method of purification of NO_x differ from when using alumina, but also obtaining a NO_x purification rate of 50 percent or more is difficult. Therefore, Japanese Patent No. 3154110 cannot serve as a document suggesting obtaining a high purification rate of 90 percent or more at 250°C or less.

DISCLOSURE OF THE INVENTION

The present invention finds that oxygen poisoning of the surface of platinum, that is, the surface of a precious metal, governs the purification rate of NO_x and provides an exhaust purification device of an internal combustion engine designed to secure a high NO_x purification rate based on this.

According to the present invention, there is provided an exhaust purification device of an internal combustion engine designed to purify NO_x generated when burning fuel under a lean air-fuel ratio by an exhaust purification catalyst arranged in an exhaust passage, which device uses as a catalyst carrier of the exhaust purification catalyst a carrier having base points on the carrier surface, carries a precious metal catalyst dispersed on the carrier surface without forming a layer of a NO_x absorbent able to absorb NO_x, and temporarily

switches air-fuel ratio of the exhaust gas flowing into the exhaust purification catalyst from lean to rich before the entire surface of the precious metal catalyst suffers from oxygen poisoning.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is an overview of a compression ignition type internal combustion engine; FIG. 2 is a view schematically showing a cross-section of the carrier surface part of an exhaust purification catalyst; FIG. 3 is a view showing the change in the air-fuel ratio of exhaust gas due to feed of a reducing agent; FIG. 4 is a view of the NO_x purification rate, FIG. 5A to FIG. 5C are views of the amount of oxygen poisoning per unit time; FIG. 6 is a view of a time chart of control for eliminating oxygen poisoning and control for releasing SO_x; FIG. 7 is a view of various fuel injection patterns; FIG. 8 is a flow chart of control of different flags; FIG. 9 and FIG. 10 are flow charts of control for feeding a reducing agent; FIG. 11A and FIG. 11B are views for explaining control of the air-fuel ratio of exhaust gas; FIG. 12 is a flow chart of control for feeding a reducing agent; FIG. 13 is a view of changes in the air-fuel ratio of exhaust gas; FIG. 14 is a flow chart of control for feeding a reducing agent; FIG. 15A and FIG. 15B are views of a particulate filter; FIG. 16 is an overview of another embodiment of a compression ignition internal combustion engine; FIG. 17 is an overview of still another embodiment of a compression ignition internal combustion engine; FIG. 18 is an overview of still another embodiment of a compression ignition internal combustion engine; FIG. 19 is a view of the NO_x purification rate; FIG. 20 is a flow chart of control for feeding a urea aqueous solution; FIG. 21 is an overview of still another embodiment of a compression ignition internal combustion engine; FIG. 22 is a view schematically illustrating a cross-section of the part of the carrier surface of a NO_x storing catalyst; FIG. 23 is

a view of changes in the air-fuel ratio of exhaust gas
due to feeding a reducing agent; FIG. 24 is a view of the
exhaust gas purification rate; FIG. 25 is a view of a
time chart of control for eliminating oxygen poisoning
5   and control for releasing SO_x; FIG. 26A and FIG. 26B are
views for explaining the amount of NO_x absorption per unit
time; FIG. 27 is a view of a time chart of control for
releasing NO_x and SO_x; FIG. 28 is a flow chart of control
for feeding a reducing agent; FIG. 29 is a flow chart of
10 processing for eliminating poisoning; FIG. 30 is a flow
chart of processing I for releasing SO_x; FIG. 31 is a flow
chart of processing for releasing NO_x; FIG. 32 is a flow
chart of processing II for releasing SO_x; FIG. 33 is a
flow chart of control for feeding a reducing agent; FIG.
15 34 is a flow chart for processing for eliminating
poisoning; FIG. 35 is a flow chart of processing for
releasing NO_x; FIG. 36 is a view showing the exhaust gas
temperature and catalyst basicity degree when releasing
NO_x; FIG. 37 is a view of the relationship between the SO_x
20 release temperature and catalyst basicity degree; FIG. 38
is an overview of still another embodiment of a
compression ignition internal combustion engine; FIG. 39
is an overview of still another embodiment of a
compression ignition internal combustion engine; FIG. 40
25 is an overview of still another embodiment of a
compression ignition internal combustion engine; FIG. 41
is an overview of still another embodiment of a
compression ignition internal combustion engine; FIG. 42
is a view of the amount of generation of smoke; FIG. 43A
30 and FIG. 43B are views of the gas temperature etc. in a
combustion chamber; FIG. 44 is a view of operating
regions I and II; FIG. 45 is a view of the air-fuel ratio
A/F; and FIG. 46 is a view of the changes in the throttle
valve opening degree etc.
35   BEST MODE FOR WORKING THE INVENTION
        FIG. 1 shows the case of application of the present
invention to a compression ignition type internal

combustion engine. Note that the present invention may also be applied to a spark ignition type internal combustion engine.

Referring to FIG. 1, 1 indicates an engine body, 2 a combustion chamber of each cylinder, 3 an electronically controlled fuel injector for injecting fuel into each combustion chamber 2, 4 an intake manifold, and 5 an exhaust manifold. The intake manifold 4 is connected through an intake duct 6 to an outlet of a compressor 7a of an exhaust turbocharger 7. The inlet of the compressor 7a is connected to an air cleaner 8. Inside the intake duct 6 is arranged a throttle valve 9 driven by a step motor. Further, around the intake duct 6 is arranged a cooling device 10 for cooling the intake air flowing through the inside of the intake duct 6. In the embodiment shown in FIG. 1, the engine cooling water is guided into the cooling device 10. The engine cooling water cools the intake air. On the other hand, the exhaust manifold 5 is connected to an inlet of an exhaust turbine 7b of the exhaust turbocharger 7, while the outlet of the exhaust turbine 7b is connected to a casing 12 housing a exhaust purification catalyst 11. The outlet of the collecting portion of the exhaust manifold 5 is provided with a reducing agent feed valve 13 for feeding a reducing agent comprised of for example a hydrocarbon into the exhaust gas flowing through the inside of the exhaust manifold 5.

The exhaust manifold 5 and the intake manifold 4 are connected through an exhaust gas recirculation (hereinafter referred to as an "EGR") passage 14. The EGR passage 14 is provided with an electronically controlled EGR control valve 15. Further, around the EGR passage 14 is arranged a cooling device 16 for cooling the EGR gas flowing through the inside of the EGR passage 14. In the embodiment shown in FIG. 1, the engine cooling water is guided into the cooling device 16. The engine cooling water cools the EGR gas. On the other hand, each fuel

injector 3 is connected through a fuel feed tube 17 to a
fuel reservoir, that is, a so-called "common rail" 18.
This common rail 18 is supplied with fuel from an
electronically controlled variable discharge fuel pump
19. The fuel supplied into the common rail 18 is supplied
through each fuel feed tube 17 to the fuel injector 3.

An electronic control unit 30 is comprised of a
digital computer provided with a ROM (read only memory)
32, a RAM (random access memory) 33, a CPU
(microprocessor) 34, an input port 35, and an output port
36 all connected to each other by a bidirectional bus 31.
The exhaust purification catalyst 11 is provided with a
temperature sensor 20 for detecting the temperature of
the exhaust purification catalyst 11. The output signal
of the temperature sensor 20 is input to the input port
35 through a corresponding AD converter 37. Further, the
exhaust pipe 21 connected to the outlet of the casing 12
if necessary has various types of sensors 22 arranged in
it. An accelerator pedal 40 has a load sensor 41
generating an output voltage proportional to the amount
of depression L connected to it. The output voltage of
the load sensor 41 is input to the input port 35 through
a corresponding AD converter 37. Further, the input port
35 has a crank angle sensor 42 generating an output pulse
each time the crankshaft turns for example by 15 degrees
connected to it. On the other hand, the output port 36 is
connected through corresponding drive circuits 38 to the
fuel injectors 3, throttle valve driving step motor 9,
EGR control valve 15, and fuel pump 19.

The exhaust purification catalyst 11 shown in FIG. 1
is comprised of a monolithic catalyst. A base of the
exhaust purification catalyst 11 carries a catalyst
carrier. FIG. 2 schematically shows the cross-section of
the surface part of this catalyst carrier 50. As shown in
FIG. 2, the catalyst carrier 50 carries a precious metal
catalyst 51 dispersed on its surface. In the present
invention, as the catalyst carrier 50, a carrier 50 on

the surface of which there are base points exhibiting
basicity is used. Further, in this embodiment of the
present invention, platinum is used as the precious metal
catalyst 51.

In this way, in this embodiment, the surface of the
catalyst carrier 50 made of alumina carries only platinum
51 and is not formed with a layer of an NO_x absorbent
comprised of an alkali metal or alkali earth able to
absorb NO_x. The inventors studied an exhaust purification
catalyst 11 comprised of a carrier 50 made of alumina
carrying only platinum 51 on its surface and as a result
learned that with such an exhaust purification catalyst
11, if temporarily making the air-fuel ratio rich when
burning fuel under a lean air-fuel ratio, a NO_x
purification rate of 90 percent or more can be obtained
when the temperature of the exhaust purification catalyst
11 is a low temperature of 250°C or less.

The inventors engaged in studies on the reasons for
this from various angles and as a result reached the
conclusion that when purifying NO_x, an action of direct
breakdown of NO_x at the surface of the platinum 51 or
action of selective reduction of NO_x or an action of
adsorption of NO_x on the catalyst carrier 50 or action of
holding the NO_x on the catalyst carrier 50 occur
simultaneously in parallel and that due to these actions
occurring simultaneously in parallel, a high NO_x
purification rate of 90 percent or more is obtained.

That is, platinum 51 inherently has activity at a
low temperature. The first action which occurs when NO_x is
being purified is the action, when the air-fuel ratio of
the exhaust gas is lean, of the NO_x in the exhaust gas
being absorbed on the surface of the platinum 51 in the
state separated into N and O and the separated N forming
N_2 and being diassociated from the platinum 51, that is,
action of direct breakdown of NO_x. This direct breakdown
action forms part of the NO_x purification action.

The second action which occurs when NO_x is being

purified is the action, when the air-fuel ratio of the exhaust gas is lean, of the NO_x adsorbed on the surface of the platinum 51 being selectively reduced by the HC adsorbed on the catalyst carrier 50. This NO_x selective reduction action forms part of the NO_x purification action.

On the other hand, the NO_x in the exhaust gas, that is, the NO, is oxidized on the surface of the platinum 51 to become NO_2 and is further oxidized to become nitrate ions NO_3^-. The third action which occurs when NO_x is being purified is the action of the NO_2 being adsorbed on the catalyst carrier 50. This adsorption action forms part of the NO_x purification action. Further, the catalyst carrier 50 made of alumina has base points on its surface. The fourth action which occurs when NO_x is being purified is the action of the nitrate ions NO_3^- being held at the base points on the surface of the catalyst carrier 10. This holding action forms part of the NO_x purification action.

In this way, when NO_x is being purified, these various actions occur simultaneously. As a result, a high purification rate of 90 percent or more is obtained.

However, if exposing an exhaust purification catalyst 11 comprised of a catalyst carrier 50 made of alumina on which only platinum 51 is carried to exhaust gas of a lean air-fuel ratio, the NO_x purification rate gradually falls. This is because the surface of the platinum 51 becomes covered by oxygen atoms, that is, the surface of the platinum 51 suffers from oxygen poisoning, whereby the direct breakdown of NO_x or selective reduction of NO_x on the surface of the platinum 51 becomes difficult. That is, if the surface of the platinum 51 is covered by oxygen atoms, the NO in the exhaust gas will no longer be able to be adsorbed on the surface of the platinum 51, so direct breakdown of the NO_x will become difficult. If the surface of the platinum 51 is covered by oxygen atoms, the NO will no longer be able to be absorbed on the surface of the platinum 51, so the

selective reduction of the NO_x will become difficult.

However, if temporarily making the air-fuel ratio rich at this time, the oxygen atoms covering the surface of the platinum 51 will be consumed for oxidation of the HC or CO, that is, the oxygen poisoning of the surface of the platinum 51 will be eliminated, therefore when the air-fuel ratio is returned to lean, direct breakdown of NO_x or selective reduction of NO_x again becomes performed well.

However, if the surface of the platinum 51 is covered by oxygen atoms, the NO_x will easily be oxidized on the surface of the platinum 51 and therefore the amount of the NO_x adsorbed or held on the catalyst carrier 50 will increase. Despite this, the fact that the NO_x purification rate drops means that the direct breakdown of the NO_x or the selective reduction of the NO_x governs the NO_x purification action. Therefore, when carrying only platinum 51 on a catalyst carrier 50 made of alumina, preventing the surface of the platinum 51 as a whole from becoming poisoned by oxygen is the most important issue. Therefore, it becomes necessary to temporarily switch the air-fuel ratio of the exhaust gas from lean to rich before the entire surface of the platinum 51 suffers from oxygen poisoning.

Next, this will be explained with reference to experimental results.

FIG. 3 shows the case of injecting a reducing agent from a reducing agent feed valve 13 for exactly the time t1 at time intervals of the time t2 and thereby maintaining the air-fuel ratio of the exhaust gas flowing into the exhaust purification catalyst 11 (ratio of the amount of air supplied to the intake passage, the combustion chambers 2, and the exhaust passage upstream of the exhaust purification catalyst and the amount of fuel and reducing agent) lean for exactly the time t2, then making it rich for exactly the time t1.

FIG. 4 shows the relationship between the

temperature TC (°C) of the exhaust purification catalyst 11 and the NO_x purification rate (%) when temporarily switching the air-fuel ratio of the exhaust gas flowing into the exhaust purification catalyst 11 from lean to rich for exactly the time t1 shown in FIG. 3 before the entire surface of the platinum 51 suffers from oxygen poisoning in an exhaust purification catalyst 11 comprised of a catalyst carrier 50 made of alumina on which only platinum 51 is carried. Note that FIG. 4 shows the case where the amount of coating of the catalyst carrier 50 made of the alumina is 150 (g) and the amount of platinum 51 carried is 3 (g).

From FIG. 4, it will be understood that a NO_x purification rate of 90 percent or more, that is, close to 100 percent, is obtained when the temperature TC of the exhaust purification catalyst 11 is a low temperature of 250°C or less. Note that it is learned that when the temperature TC of the exhaust purification catalyst 11 becomes 200°C or less, the NO_x purification rate falls somewhat, but even if the temperature TC of the exhaust purification catalyst 11 falls to 150°C, the NO_x purification rate is 80 percent or more and is still high. Further, if the temperature TC of the exhaust purification catalyst 11 becomes higher than 250°C, the NO_x purification rate will gradually fall. That is, if the temperature TC of the exhaust purification catalyst 11 becomes higher, the NO will have difficultly being adsorbed on the surface of the platinum 51 and as a result not only will the direct breakdown action of the NO_x become difficult, but also the selective reduction action of the NO_x will becomes difficult, so the NO_x purification rate will gradually fall.

Note that even if increasing the amount of the platinum 51 carried over 3 (g), the NO_x purification rate will not increase much at all, but if reducing the amount of platinum 51 carried to less than 3 (g), the NO_x

purification rate will fall.

Further, FIG. 4 shows the case of making the lean time t2 when the air-fuel ratio of the exhaust gas is lean in FIG. 3 60 seconds and making the rich time 51 where the air-fuel ratio of the exhaust gas is made rich 3 seconds. In this case, a rich time t1 of 3 seconds is sufficient to completely eliminate the oxygen poisoning of the platinum 51, so if seen from the viewpoint of eliminating the oxygen poisoning, there is no sense even if making the rich time t1 more than 3 seconds. As opposed to this, if making the rich time 51 shorter than 3 seconds, the NO_x purification rate will gradually fall.

Further, it is also possible to use rhodium as the precious metal catalyst 51 in addition to platinum. In this case, in FIG. 4, the region of the temperature TC (°C) where the NO_x purification rate becomes 90 percent or more spreads to the high temperature side and the NO_x purification rate at the high temperature side becomes higher.

If temporarily switching the air-fuel ratio of the exhaust gas flowing into the exhaust purification catalyst 11 from lean to rich before the precious metal catalyst 51 suffers from oxygen poisoning at its entire surface, it is possible to obtain a NO_x purification rate of 90 percent or more. Note that if temporarily switching the air-fuel ratio of the exhaust gas from lean to rich, the NO_2 adsorbed on the catalyst carrier 50 or the nitrate ions NO_3^- held on the catalyst carrier 50 will be reduced by the HC and CO. That is, if temporarily switching the air-fuel ratio of the exhaust gas from lean to rich so as to eliminate the oxygen poisoning of the surface of the precious metal catalyst 51, the NO_x adsorbed or held on the catalyst carrier 50 will be removed and therefore when the air-fuel ratio is returned from rich to lean, the NO_x adsorption action or the nitrate ion NO_3^- holding action will be started again.

As explained above, when carrying only platinum 51

on a catalyst carrier 50 made of alumina, the direct breakdown of the NO_x and selective reduction of the NO_x will govern the NO_x purification rate. However, the action of adsorption of NO_2 to the catalyst carrier 50 and the

5 action of holding nitrate ions NO_3^- on the catalyst carrier 50 also contribute to purification of NO_x. However, it has been known in the past that if there is NO_2 in the exhaust gas, some NO_2 will be adsorbed on the catalyst no matter what the catalyst. In this embodiment

10 of the present invention, the NO in the exhaust gas is oxidized at the platinum 51, whereby NO_2 is produced and therefore NO_2 is adsorbed on the exhaust purification catalyst 11.

As opposed to this, the nitrate ions NO_3^- are not

15 held at all catalysts. In order to get nitrate ions NO_3^- held on a catalyst, the surface of the catalyst must exhibit basicity. In the embodiment according to the present invention, as explained above, since the catalyst carrier 50 is comprised of alumina, the catalyst carrier

20 50 has base points having basicity on its surface and therefore the nitrate ions NO_3^- are held at the base points present on the surface of the catalyst carrier 50.

However, the basicity of the base points present on the surface of a catalyst carrier 50 comprised of alumina

25 is not that strong. Therefore, the holding force on the nitrate ions NO_3^- is also not that strong. Accordingly, if the temperature TC of the exhaust purification catalyst 11 rises, the NO_x held on the exhaust purification catalyst 11 is disassociated from the exhaust

30 purification catalyst 11. As shown in FIG. 4, the NO_x purification rate gradually falls along with the rise of the temperature TC of the exhaust purification catalyst 11 because of the presence of this NO_x disassociation action.

35 On the other hand, the higher the basicity of the base points on the surface of the catalyst carrier 50, the greater the amount of NO_x held in the form of nitrate

ions NO_3^-. Therefore, to get the amount of NO_x held on the exhaust purification catalyst 11 to increase, it is sufficient to increase the number of base points or raise the basicity of the base points. In this case, as shown by reference numeral 52 in FIG. 2, if adding to the inside of the catalyst carrier 50 made of alumina at least one element selected from potassium K, sodium Na, lithium Li, cesium Cs, rubidium Rb, or another alkali metal, barium Ba, calcium Ca, strontium Sr, or another alkali earth, lanthanum La, yttrium Y, or another rare earth, it is possible to increase the number of base points or raise the basicity of the base points. In this case, these lanthanum La, barium Ba, or other additive 52 can be added to the inside of the catalyst carrier 50 so as to form part of the crystal structure of the alumina for stabilization of the structure or can be added to the inside of the catalyst carrier 50 so as to form a salt between the alumina and additive 52. Note that only naturally if increasing the amount of the lanthanum La, barium Ba, or other additive 52, the amount of NO_x held at the exhaust purification catalyst 11 increases when the air-fuel ratio of the exhaust gas is lean.

On the other hand, if raising the basicity of the base points in this way, the holding force on the nitrate ions NO_3^- becomes stronger. Therefore, the nitrate ions NO_3^- become harder to disassociate even if the temperature TC of the exhaust purification catalyst 11 rises. Therefore, if raising the basicity of the base points, the NO_x purification rate at the high temperature side becomes higher in FIG. 4.

However, exhaust gas also includes SO_2. This SO_2 is oxidized on the platinum 51 and becomes SO_3. Next, this SO_3 is further oxidized on the platinum 51 and becomes sulfate ions SO_4^{2-}. If the catalyst has basicity, the sulfate ions SO_4^{2-} are held on the catalyst. Further, the sulfate ions SO_4^{2-} are held on the catalyst more easily than the nitrate ions NO_3^-. Therefore, if nitrate ions NO_3^-

are held on the catalyst, sulfate ions SO_4^{2-} will also
necessarily be held on the catalyst. In this embodiment
according to the present invention, nitrate ions NO_3^- are
held on the catalyst carrier 50. Therefore, in this
5   embodiment according to the present invention, the
sulfate ions SO_4^{2-} are also held on the catalyst carrier
50.

On the other hand, as explained at the start, if
forming a layer of a NO_x absorbent comprised of an alkali
10   metal or alkali earth on the catalyst carrier, SO_x forms a
sulfate in the layer of the NO_x absorbent. However, this
sulfate is hard to break down. Unless raising the
temperature of the catalyst to 600°C or more and making
the air-fuel ratio of the exhaust gas rich in that state,
15   it is not possible to get the SO_x released from the
catalyst.

However, in this embodiment, the basicity of the
base points present on the surface of the catalyst
carrier 50 comprised of the alumina is extremely low
20   compared with the basicity of the NO_x absorbent.
Therefore, the SO_x is held at the base points on the
surface of the catalyst carrier 50 not in the form of a
sulfate, but in the form of sulfate ions SO_4^{2-}. Further,
in this case, the holding force on the sulfate ions SO_4^{2-}
25   is considerably small.

If the holding force on the sulfate ions SO_4^{2-} is
small in this way, the sulfate ions SO_4^{2-} will break down
and disassociate at a low temperature. In fact, in this
embodiment, if raising the temperature TC of the exhaust
30   purification catalyst 11 to about 500°C and making the
air-fuel ratio of the exhaust gas rich, it is possible to
get the SO_x held at the exhaust purification catalyst 11
released from the exhaust purification catalyst 11.

However, as explained above, by adding lanthanum La,
35   barium Ba, or another additive 52 to the catalyst carrier
50 so as to raise the basicity of the base points on the
surface of the catalyst carrier 50, it is possible to

increase the amount of NO_x held on the catalyst carrier 50 when the air-fuel ratio of the exhaust gas is lean and therefore in particular possible to raise the NO_x purification rate at the high temperature side. However,

5   if raising the basicity of the base points of the surface of the catalyst carrier 50, the amount of SO_x held on the catalyst carrier 50 will increase and further the holding force on the SO_x will increase. As a result, the SO_x release temperature of the exhaust purification catalyst

10   11 required for releasing the SO_x will rise.

Note that as the catalyst carrier 50, not only alumina, but also various other carriers known from the past can be used so long as they are carriers having base points on the catalyst carrier surface.

15   Next, the processing of the NO_x and SO_x will be explained based on specific embodiments.

First, a first embodiment of calculating the amount of oxygen poisoning of the precious metal catalyst, for example, the platinum 51, switching the air-fuel ratio of

20   the exhaust gas from lean to rich when the calculated amount of oxygen poisoning exceeds a predetermined allowable value, and thereby eliminating oxygen poisoning of the platinum 51 will be explained.

As shown in FIG. 5A, the amount W of oxygen

25   poisoning of platinum 51 per unit time is proportional to the oxygen concentration in the exhaust gas. Further, as shown in FIG. 5B, the amount W of oxygen poisoning of platinum 51 per unit time increases the higher the temperature of the exhaust purification catalyst 11.

30   Here, the oxygen concentration in the exhaust gas and the temperature of the exhaust purification catalyst 11 are determined from the operating state of the engine. That is, these are functions of the fuel injection amount Q and engine speed N. Therefore, the amount W of the oxygen

35   poisoning of the platinum 51 per unit time becomes a function of the fuel injection amount Q and engine speed N. In the first embodiment, the amount W of oxygen

poisoning of the platinum 51 per unit time is found in advance by experiments in accordance with the fuel injection amount Q and engine speed N. This amount W of oxygen poisoning is stored as a function of the fuel injection amount Q and engine speed N in advance in the form of a map in the ROM 32 as shown in FIG. 5C.

FIG. 6 shows a time chart of the control for eliminating oxygen poisoning and the control for releasing SO_x. As shown in FIG. 6, each time the cumulative value ΣW of the amount W of oxygen poisoning exceeds the allowable value WX, a reducing agent is supplied from the reducing agent feed valve 13 and the air-fuel ratio A/F of the exhaust gas flowing into the exhaust purification catalyst 11 is temporarily switched from lean to rich. At this time, the oxygen poisoning of the platinum 51 is eliminated and the NO_x adsorbed or held on the catalyst carrier 50 is released from the catalyst carrier 50 and reduced.

On the other hand, the cumulative value ΣSOX of the amount of SO_x held on the exhaust purification catalyst 11 is also calculated and, when the cumulative value ΣSOX of the amount of SO_x exceeds an allowable value SX, the action of releasing SO_x from the exhaust purification catalyst 11 is performed. That is, first, the temperature TC of the exhaust purification catalyst 11 is raised to the SO_x release temperature TX. The SO_x release temperature TX is about 500°C when no additive 52 is added to the catalyst carrier 41. When additive 52 is added to the catalyst carrier 51, it is a temperature between about 500°C to 550°C depending on the amount of addition of the additive 52.

When the temperature TC of the exhaust purification catalyst 11 reaches the SO_x release temperature TX, the air-fuel ratio of the exhaust gas flowing into the exhaust purification catalyst 11 is switched from lean to rich and the SO_x starts to be released from the exhaust

purification catalyst 11. While the SO_x is being released, the temperature TC of the exhaust purification catalyst 11 is held at the SO_x release temperature TX or more and the air-fuel ratio of the exhaust gas is held rich. Next, when the SO_x release action ends, the action of raising the temperature of the exhaust purification catalyst 11 is stopped and the air-fuel ratio of the exhaust gas is returned to lean.

As explained above, when SO_x should be released from the exhaust purification catalyst 11, the temperature of the exhaust purification catalyst 11 is raised until reaching the NO_x release temperature TX. Next, the method of raising the temperature TC of the exhaust purification catalyst 11 will be explained with reference to FIG. 7.

One of the methods effective for raising the temperature TC of the exhaust purification catalyst 11 is the method of retarding the fuel injection timing to compression top dead center or on. That is, normally the main fuel Q_m, in FIG. 7, is injected near compression top dead center as shown by (I). In this case, as shown by (II) of FIG. 7, if the injection timing of the main fuel Q_m is retarded, the after burn time becomes longer and therefore the exhaust gas temperature rises. If the exhaust gas temperature rises, the temperature TC of the exhaust purification catalyst 11 will rise along with it.

Further, to raise the temperature TC of the exhaust purification catalyst 11, as shown by (III) of FIG. 7, it is possible to inject auxiliary fuel Q_v near suction top dead center in addition to the main fuel Q_m. If additionally injecting auxiliary fuel Q_v in this way, the fuel which can be burned is increased by exactly the auxiliary fuel Q_v, so the exhaust gas temperature rises and therefore the temperature TC of the exhaust gasc 11 rises.

On the other hand, if injecting auxiliary fuel Q_v near suction top dead center in this way, during the compression stroke, the heat of compression causes

aldehydes, ketones, peroxides, carbon monoxide, and other intermediate products to be produced from this auxiliary fuel Qv. These intermediate products cause the reaction of the main fuel Qm to be accelerated. Therefore, in this case, as shown by (III) of FIG. 7, even if greatly retarding the injection timing of the main fuel Qm, good combustion is obtained without causing misfires. That is, since it is possible to greatly retard the injection timing of the main fuel Qm in this way, the temperature of the exhaust gas becomes considerably higher and therefore the temperature TC of the exhaust purification catalyst 11 can be made to quickly rise.

Further, the temperature TC of the exhaust purification catalyst 11 may be made to rise as shown in (IV) of FIG. 7 by injecting auxiliary fuel Qp in addition to the main fuel Qm during the expansion stroke or the exhaust stroke. That is, in this case, the majority of the auxiliary fuel Qp is exhausted into the exhaust passage in the form of unburned HC without being burned. This unburned HC is oxidized by the excess oxygen in the exhaust purification catalyst 11. The heat of oxidation reaction occurring at that time causes the temperature TC of the exhaust purification catalyst 11 to rise.

FIG. 8 shows a routine for control of an oxygen poisoning elimination flag showing that oxygen poisoning of the platinum 51 should be eliminated and a SO_x release flag showing that SO_x should be released. This routine is executed by interruption every predetermined time interval.

Referring to FIG. 8, first, at step 100, the amount W of oxygen poisoning per unit time is calculated from the map shown in FIG. 5C. Next, at step 101, the amount W of oxygen poisoning is added to ΣW to calculate the cumulative value ΣW of the amount of oxygen poisoning. Next, at step 102, it is judged if the cumulative value ΣW of the amount of oxygen poisoning has exceeded an

allowable value WX, that is, if the situation is a little before the entire surface of the platinum 51 suffers from oxygen poisoning. When $\Sigma W \leq WX$, the routine jumps to step 104. As opposed to this, when $\Sigma W > WX$, the routine proceeds to step 103, where the poisoning elimination flag is set, then the routine proceeds to step 104.

At step 104, the value $k \cdot Q$ of a constant k multiplied with the fuel injection amount Q is added to ΣSOX. The fuel contains a certain amount of sulfur. Therefore, the amount of SO_x held in the exhaust purification catalyst 11 per unit time can be expressed by $k \cdot Q$. Therefore, the ΣSOX obtained by adding ΣSOX to $k \cdot Q$ expresses the cumulative value of the amount of SO_x held on the exhaust purification catalyst 11. Next, at step 105, it is judged if the cumulative amount ΣSOX of the amount of SO_x exceeds an allowable value SX. When $\Sigma SOX \leq SX$, the processing cycle is ended. When $\Sigma SOX > SX$, the routine proceeds to step 106, where the SO_x release flag is set.

Next, a routine for control for feeding a reducing agent will be explained while referring to FIG. 9.

Referring to FIG. 9, first, at step 200, it is judged if the poisoning elimination flag is set. When the poisoning elimination flag is not set, the routine jumps to step 208. As opposed to this, when the poisoning elimination flag is set, the routine proceeds to step 201, where it is judged if the temperature of the exhaust purification catalyst 11 is lower than an allowable temperature TL. This allowable temperature TL is for example the temperature TC of the exhaust purification catalyst 11 when the NO_x purification rate becomes 30 percent. When carrying only platinum 51 on a catalyst carrier 50 made of alumina, this allowable temperature TL is about 400°C. When $TC \geq TL$, that is, when a high NO_x purification rate cannot be obtained even if periodically making the air-fuel ratio of the exhaust gas rich, the

routine jumps to step 208. That is, when the temperature TC of the exhaust purification catalyst 11 exceeds about 400°C, the action of switching the air-fuel ratio from lean to rich is prohibited. As opposed to this, when TC<TL, that is, when a high NO_x purification rate can be obtained by periodically making the air-fuel ratio of the exhaust gas rich, the routine jumps to step 202.

At step 202, the feed amount of the reducing agent required for making the air-fuel ratio of the exhaust gas a rich air-fuel ratio of for example about 13 is calculated. Next, at step 203, the feed time of the reducing agent is calculated. This reducing agent feed time is normally 10 seconds or less. Next, at step 204, the feed of the reducing agent from the reducing agent feed valve 13 is started. Next, at step 205, it is judged if the feed time of the reducing agent calculated at step 203 has elapsed. When the feed time of the reducing agent has not elapsed, the routine jumps to step 208, where the feed of the reducing agent is continued and the air-fuel ratio of the exhaust gas is maintained at the rich air-fuel ratio of about 13. As opposed to this, when the feed time of the reducing agent has elapsed, that is, when the oxygen poisoning of the platinum 51 has been eliminated, the routine proceeds to step 206, where the feed of the reducing agent is stopped, then the routine proceeds to step 207, where the ΣW and the oxygen poisoning elimination flag are cleared. Next, the routine proceeds to step 208.

At step 208, it is judged if the SO_x release flag has been set. When the SO_x release flag has not been set, the processing cycle is ended. As opposed to this, when the SO_x release flag has been set, the routine proceeds to step 209, where the control is performed for raising the temperature of the exhaust purification catalyst 11. That is, the fuel injection pattern from the fuel injector 3 is changed to an injection pattern of any of (II) to (IV) of FIG. 7. If the fuel injection pattern is changed to

any injection pattern of (II) to (IV) of FIG. 7, the
exhaust gas temperature rises and therefore the
temperature of the exhaust purification catalyst 11
rises. Next, the routine proceeds to step 210.

5   At step 210, it is judged if the temperature TC of
the exhaust purification catalyst 11 detected by the
temperature sensor 20 has reached the SO_x release
temperature TX or more. When TC<TX, the processing cycle
is ended. As opposed to this, when TC≥TX, the routine
10   proceeds to step 211, where the feed amount of the
reducing agent required for making the air-fuel ratio of
the exhaust gas a rich air-fuel ratio of about 14 is
calculated. Next, at step 212, the feed time of the
reducing agent is calculated. The feed time of the
15   reducing agent is several minutes. Next, at step 213, the
feed of the reducing agent from the reducing agent feed
valve 13 is started. Next, at step 214, it is judged if
the feed time of the reducing agent calculated at step
212 has elapsed. When the feed time of the reducing agent
20   has not elapsed, the processing cycle is ended. At this
time, the feed of the reducing agent is continued and the
air-fuel ratio of the exhaust gas is maintained at the
rich air-fuel ratio of about 14. As opposed to this, when
the feed time of the reducing agent has elapsed, that is,
25   when the release of the SO_x held in the exhaust
purification catalyst 11 has been completed, the routine
proceeds to step 215, where the feed of the reducing
agent is stopped. Next, at step 216, the action of
raising the temperature of the exhaust purification
30   catalyst 11 is stopped, then the routine proceeds to step
217, where the ΣSOX, ΣW, and SO_x release flag are
cleared.

          FIG. 11A, FIG. 11B, and FIG. 12 show another
embodiment. In this embodiment, as the sensor 22 arranged
35   in the exhaust pipe 21, a NO_x concentration sensor able to
detect the concentration of NO_x in the exhaust gas is
used. This NO_x concentration sensor 22, as shown in FIG.

11B, generates an output voltage V proportional to the NO_x concentration.

If the oxygen poisoning of the platinum 51 progresses, the NO_x purification rate gradually falls. As a result, the NO_x concentration in the exhaust gas gradually increases. Therefore, the amount of oxygen poisoning of the precious metal catalyst, for example, the platinum 51, can be estimated from the NO_x concentration in the exhaust gas. In this embodiment, when the amount of oxygen poisoning estimated from the NO_x concentration in the exhaust gas exceeds a predetermined allowable value, that is, as shown in FIG. 11A, when the output voltage V of the NO_x concentration sensor 22 exceeds a set value VX, the air-fuel ratio of the exhaust gas is switched from lean to rich.

FIG. 12 shows the routine for control for feeding a reducing agent in this embodiment.

Referring to FIG. 12, first, at step 300, it is judged if the output voltage V of the NO_x concentration sensor 22 has exceeded a set value VX. When V≤VX, the routine jumps to step 208 of FIG. 10. As opposed to this, when V>VX, the routine proceeds to step 301, where the feed amount of the reducing agent required for making the air-fuel ratio of the exhaust gas the rich air-fuel ratio of about 13 is calculated. Next, at step 302, the feed time of the reducing agent is calculated. This feed time of the reducing agent is normally 10 seconds or less. Next, at step 303, the feed of the reducing agent from the reducing agent feed valve 13 is started. Next, at step 304, it is judged if the feed time of the reducing agent calculated at step 302 has elapsed. When the feed time of the reducing agent has not elapsed, the routine jumps to step 208 of FIG. 10, where the feed of the reducing agent is continued and the air-fuel ratio of the exhaust gas is maintained at a rich air-fuel ratio of about 13. As opposed to this, when the feed time of the reducing agent has elapsed, that is, when the oxygen

poisoning of the platinum 51 has been eliminated, the
routine proceeds to step 305, where the feed of the
reducing agent is stopped, then the routine proceeds to
step 208 of FIG. 10.

5   Note that in this embodiment as well, the routine
for control of the flags shown in FIG. 8 is used, but in
this embodiment, it is not necessary to calculate the
amount W of oxygen poisoning, so in the routine for
control of the flags shown in FIG. 8, only step 104 to
10   step 106 are executed. Further, in this embodiment, as
explained above, after the routine shown in FIG. 12, the
routine shown in FIG. 10 is executed, but at step 217 in
the routine shown in FIG. 10, only the ΣSOX and SO_x
release flag are cleared.

15   FIG. 13 and FIG. 14 show still another embodiment.
In this embodiment, to eliminate the oxygen poisoning of
the precious metal catalyst, for example, the platinum
51, it is judged if the oxygen poisoning of the platinum
51 has been eliminated when the air-fuel ratio of the
20   exhaust gas is made rich. When it is judged that the
oxygen poisoning of the platinum 51 has been eliminated,
the air-fuel ratio of the exhaust gas is switched from
rich to lean.

        More specifically speaking, in this embodiment, as
25   the sensor 22 arranged in the exhaust pipe 21, an air-
fuel ratio for detecting the air-fuel ratio of the
exhaust gas flowing out from the exhaust purification
catalyst 11 is used. As shown in FIG. 13, when the air-
fuel ratio (A/F) of the exhaust gas flowing into the
30   exhaust purification catalyst 11 is switched from lean to
rich, that is, when a reducing agent is supplied from the
reducing agent feed valve 13, the reducing agent, that
is, the hydrocarbon, is oxidized by the oxygen on the
platinum 51. While there is oxygen on the platinum 51,
35   the air-fuel ratio (A/F) out of the exhaust gas flowing out
from the exhaust purification catalyst 11 is maintained
at about the stoichiometric air-fuel ratio. Next, when

there is no longer any oxygen on the platinum 51, the
hydrocarbon passes through the exhaust purification
catalyst 11, so the air-fuel ratio(A/F)out of the exhaust
gas flowing out from the exhaust purification catalyst 11
5   becomes rich. Therefore, when the air-fuel ratio(A/F)in
of the exhaust gas flowing into the exhaust purification
catalyst 11 is switched from lean to rich, it is possible
to judge that the oxygen poisoning of the platinum 51 has
been eliminated when the air-fuel ratio(A/F)out of the
10   exhaust gas flowing out from the exhaust purification
catalyst 11 becomes rich.
        FIG. 14 shows a routine for control for feeding a
reducing agent in this embodiment.
        Referring to FIG. 14, first, at step 400, it is
15   judged if the poisoning elimination flag has been set.
When the poisoning elimination flag has not been set, the
routine jumps to step 208 of FIG. 10. As opposed to this,
when the poisoning elimination flag is set, the routine
proceeds to step 401, where the feed amount of the
20   reducing agent required for making the air-fuel ratio of
the exhaust gas a rich air-fuel ratio of about 13 or so
is calculated. Next, the routine proceeds to step 402,
where the feed of the reducing agent from the reducing
agent feed valve 13 is started. Next, at step 403, it is
25   judged if the air-fuel ratio(A/F)out of the exhaust gas
detected by the air-fuel ratio sensor 22 has become rich.
When the air-fuel ratio(A/F)out is not rich, the routine
jumps to step 208 of FIG. 10. As opposed to this, when
the air-fuel ratio(A/F)out becomes rich, that is, when
30   the oxygen poisoning of the platinum 51 is eliminated,
the routine proceeds to step 404, where the feed of the
reducing agent is stopped, then the routine proceeds to
step 405, where the ΣW and poisoning elimination flag are
cleared. Next, the routine proceeds to step 208 of FIG.
35   10.
        Next, an embodiment using a particulate filter
instead of the exhaust purification catalyst 11 will be

explained.

FIG. 15A and FIG. 15B show the structure of this particulate filter 11. Note that FIG. 15A is a front view of the particulate filter 11, while FIG. 15B is a side sectional view of the particulate filter 11. As shown in FIGS. 15A and 15B, the particulate filter 11 forms a honeycomb structure and is provided with a plurality of exhaust passage pipes 60 and 61 extending in parallel with each other. These exhaust passage pipes are comprised by exhaust gas inflow passages 60 with downstream ends sealed by plugs 62 and exhaust gas outflow passages 61 with upstream ends sealed by plugs 63. Note that the hatched portions in FIG. 15A show plugs 63. Therefore, the exhaust gas inflow passages 60 and the exhaust gas outflow passages 61 are arranged alternately through thin wall partitions 64. In other words, the exhaust gas inflow passages 60 and the exhaust gas outflow passages 61 are arranged so that each exhaust gas inflow passage 60 is surrounded by four exhaust gas outflow passages 61, and each exhaust gas outflow passage 61 is surrounded by four exhaust gas inflow passages 60.

The particulate filter 11 is formed from a porous material such as for example cordierite. Therefore, the exhaust gas flowing into the exhaust gas inflow passages 60 flows out into the adjoining exhaust gas outflow passages 61 through the surrounding partitions 64 as shown by the arrows in FIG. 15B.

In this embodiment, the peripheral walls of the exhaust gas inflow passages 60 and exhaust gas outflow passages 61, that is, the surfaces of the two sides of the partitions 64 and inside walls of the fine holes of the partitions 64 are formed on them with a layer of a catalyst carrier comprised of alumina. The catalyst carrier carries a precious metal catalyst on it. Note that in this embodiment, platinum Pt is used as the precious metal catalyst.

In this embodiment as well, platinum is carried on

the catalyst carrier made of alumina. Therefore, in this embodiment as well, the NO_x purification rate shown in FIG. 4 is obtained.

Further, in this embodiment, the particulate contained in the exhaust gas is trapped in the particulate filter 11 and the trapped particulate is successively made to burn by the heat of the exhaust gas. If a large amount of particulate deposits on the particulate filter 11, the injection pattern is switched to any one of the injection patterns (II) to (IV) of FIG. 7 and the exhaust gas temperature is made to rise. Due to this, the deposited particulate is ignited and burned.

FIG. 16 and FIG. 17 show other embodiments of a compression ignition internal combustion engine.

In the embodiment shown in FIG. 16, the exhaust passage upstream of the exhaust purification catalyst 11 has arranged in it an exhaust purification catalyst the same as the exhaust purification catalyst 11 or a particulate filter or NO_x selective reducing catalyst 23 having the function of selectively reducing NO_x but not having the function of absorbing NO_x. In the embodiment shown in FIG. 17, the exhaust passage downstream of the exhaust purification catalyst 11 has arranged in it a particulate filter or a NO_x selective reducing catalyst 23 having the function of selectively reducing NO_x, but not having the function of absorbing NO_x.

If arranging in the exhaust passage upstream of the exhaust purification catalyst 11 an exhaust purification catalyst 23 the same as the exhaust purification catalyst 11, the downstream exhaust purification catalyst 11 will become lower in temperature than the upstream exhaust purification catalyst 23, so when the temperature of the upstream exhaust purification catalyst 23 becomes high and the NO_x purification rate drops, a high NO_x purification rate can be obtained at the downstream exhaust purification catalyst 11. Further, the particulate filter 23 may be one not having a precious

metal catalyst and catalyst carrier or one having a
precious metal catalyst and a catalyst carrier. Further,
as the NO_x selective reducing catalyst 23, a Cu-zeolite
catalyst may be used. However, a Cu-zeolite catalyst 23

5   is low in heat resistance, so when using a Cu-zeolite
catalyst 23, as shown in FIG. 17, it is preferable to
arrange the Cu-zeolite catalyst 23 at the downstream side
of the exhaust purification catalyst 11. Note that in the
embodiments shown in FIG. 16 and FIG. 17 as well, the

10   feed of the reducing agent is controlled by a method
similar to the method shown in FIG. 6.

FIG. 18 shows still another embodiment of the
compression ignition internal combustion engine.

In this embodiment, the exhaust passage downstream

15   of the exhaust purification catalyst 11 has arranged in
it a NO_x selective reducing catalyst 24 having the
function of selectively reducing NO_x, but not having the
function of absorbing NO_x. As this NO_x selective reducing
catalyst 24, use is made of a catalyst V_2O_3/TiO_2 having

20   titania as a carrier and carrying vanadium oxide on this
carrier (hereinafter referred to as a "vanadium-titania
catalyst") or a catalyst Cu/ZSM 5 having zeolite as a
carrier and carrying copper on the carrier (hereinafter
referred to as a "copper-zeolite carrier").

25   Further, the exhaust passage between the NO_x
selective reducing catalyst 24 and the exhaust
purification catalyst 11 has arranged in it a urea feed
valve 25 for feeding a urea aqueous solution. This urea
feed valve 25 feeds a urea aqueous solution by a feed

30   pump 26. Further, the intake passage has an intake air
detector 27 arranged inside it. A NO_x concentration sensor
is used as the sensor 22 arranged in the exhaust pipe 21.

If feeding urea aqueous solution from the urea feed
valve 25 into the exhaust gas when the air-fuel ratio of

35   the exhaust gas is lean, the NO contained in the exhaust
gas is reduced by the ammonia NH_3 generated from the urea
$CO(NH_2)_2$ on the NO_x selective reducing catalyst 24 (for

example, $2NH_3+2NH+1/2O^2 \rightarrow 2N_2+3H_2O$). In this case, a certain amount of urea is required for reducing the NO_x contained in the exhaust gas and completely removing the NO_x in the exhaust gas. Below, the amount of urea required for reducing and completely removing the NO_x in the exhaust gas will be referred to as an amount of urea of an equivalence ratio of the urea/NO_x of 1. Note that an equivalence ratio of urea/NO_x of 1 will be referred to below simply as an equivalence ratio of 1.

The solid line of FIG. 19 shows the relationship between the NO_x purification rate due to the exhaust purification catalyst 11 and the temperature TC of the exhaust purification catalyst 11 of the same value as shown in FIG. 4. The broken line of FIG. 19 shows the relationship between the NO_x purification rate when feeding a urea aqueous solution to give an amount of urea of an equivalence ratio of 1 with respect to the amount of NO_x in the exhaust gas and the temperature TC of the NO_x selective reducing catalyst 24. From FIG. 19, when a urea aqueous solution is fed so as to give an amount of urea of an equivalence ratio of 1 with respect to the amount of NO_x in the exhaust gas, if the temperature TC of the NO_x selective reducing catalyst 24 becomes about 300°C or more, the NO_x purification rate becomes about 100 percent. As the temperature TC of the NO_x selective reducing catalyst 24 falls, it is learned that the NO_x purification rate falls.

In this embodiment, the feed of the reducing agent from the reducing agent feed valve 13 is controlled by the routine for control of the flags shown in FIG. 8 and the routine for control for feeding the reducing agent shown in FIG. 10 in the region I with a temperature TC of the exhaust purification catalyst 11 lower than the set temperature TL, for example, 300°C, in FIG. 19. Therefore, a high NO_x purification rate is obtained by the exhaust purification catalyst 11 in the region I. Note that in

this case, as will be understood from FIG. 19, the TL at step 201 of FIG. 9 is 300°C.

On the other hand, in the region where the temperature TC of the NO_x selective reducing catalyst 24 is higher than the set temperature TN (<TL) in FIG. 19, a urea aqueous solution is fed by the urea aqueous solution feed control routine shown in FIG. 20, whereby the NO_x is purified by the NO_x selective reducing catalyst 24.

That is, referring to FIG. 20, first, at step 500, it is judged if the temperature TC of the NO_x selective reducing catalyst 24 is higher than a set temperature TN, for example, 250°C. When TC≤TN, the processing cycle is ended. As opposed to this, when TC>TN, the routine proceeds to step 501, where the amount of NO_x exhausted from a combustion chamber 2 per unit time is found from the NO_x concentration detected by the NO_x concentration sensor 22 and the amount of intake air detected by the intake air detector 27. Based on this amount of NO_x, the amount of urea per unit time giving an equivalence ratio of 1 with respect to the amount of NO_x is calculated. Next, at step 502, the feed amount of the urea aqueous solution is calculated from the calculated amount of urea. Next, at step 503, the amount of the urea aqueous solution calculated at step 502 is fed from the urea feed valve 13. Therefore, in the region II, a high NO_x purification rate is obtained by the NO_x selective reducing catalyst 24.

As will be understood from FIG. 19, in the region where the region I and region II overlap, the action of purification of NO_x by the exhaust purification catalyst 11 and the action of purification of NO_x by the NO_x selective reducing catalyst 24 are performed. Therefore, the NO_x purification rate in this region becomes substantially 100 percent. Therefore, a high NO_x purification rate can be obtained over a wide temperature region.

Next, another embodiment enabling a high NO_x

purification rate to be obtained over a wide temperature region will be explained.

In this embodiment, as shown in FIG. 21, a NO_x storing catalyst 29 housed in a casing 28 is arranged upstream of the exhaust purification catalyst 11. That is, in this embodiment, the casing 28 housing the NO_x storing catalyst 29 is connected to the outlet of the exhaust turbine 7b of the exhaust turbocharger 7, while the outlet of the casing 28 is connected to a casing 12 housing the exhaust purification catalyst 11 through the exhaust pipe 43.

Further, in this embodiment, in addition to the temperature sensor 20 for detecting the temperature of the exhaust purification catalyst 11, a temperature sensor 48 for detecting the temperature of the NO_x storing catalyst 29 is attached to the NO_x storing catalyst 11. The exhaust pipe 43 connecting the outlet of the NO_x storing catalyst 29 and the inlet of the exhaust purification catalyst 11 has arranged in it a temperature sensor 49 for detecting the temperature of the temperature of the exhaust gas flowing through these catalysts 29 and 11. Note that in practice at least one of these temperature sensors 20, 48, and 49 is provided.

The NO_x storing catalyst 29 shown in FIG. 21 is comprised of a monolithic catalyst. A base of the NO_x storing catalyst 29 carries a catalyst carrier made of for example alumina. FIG. 22 schematically shows the cross-section of the surface part of this catalyst carrier 45. As shown in FIG. 22, the catalyst carrier 45 carries a precious metal catalyst 46 dispersed on its surface. Further, the catalyst carrier 45 is formed on its surface with a layer of a NO_x absorbent 47.

In this embodiment, platinum Pt is used as the precious metal catalyst 46. As the ingredient forming the NO_x absorbent 47, for example, at least one element selected from potassium K, sodium Na, cesium Cs, or another alkali metal, barium Ba, calcium Ca, or another

alkali earth, lanthanum La, yttrium Y, or another rare
earth may be used.

If the ratio of the air and fuel (hydrocarbons)
supplied to the engine intake passage, combustion
5 chambers 2, and exhaust passage upstream of the NO_x
storing catalyst 29 is referred to as the "air-fuel ratio
of the exhaust gas", the NO_x absorbent 47 performs an NO_x
absorption and release action of absorbing the NO_x when
the air-fuel ratio of the exhaust gas is lean and
10 releasing the absorbed NO_x when the oxygen concentration
in the exhaust gas falls. Note that when the inside of
the exhaust passage upstream of the NO_x storing catalyst
29 is not supplied with fuel (hydrocarbons) or air, the
air-fuel ratio of the exhaust gas matches with the air-
15 fuel ratio of the air-fuel mixture supplied to the
combustion chamber 2. Therefore, in this case, the NO_x
absorbent 47 absorbs the NO_x when the air-fuel ratio of
the air-fuel mixture supplied into the combustion chamber
2 is lean, while releases the absorbed NO_x when the oxygen
20 concentration in the air-fuel mixture supplied to the
combustion chamber 2 falls.

That is, if explaining this taking as an example the
case of using barium Ba as the ingredient forming the NO_x
absorbent 47, when the air-fuel ratio of the exhaust gas
25 is lean, that is, when the oxygen concentration in the
exhaust gas is high, the NO contained in the exhaust gas
is oxidized on the platinum Pt 46 such as shown in FIG.
22 to become NO_2, then is absorbed in the NO_x absorbent 47
and diffuses in the NO_x absorbent 47 in the form of
30 nitrate ions NO_3^- while bonding with the barium oxide BaO.
In this way, the NO_x is absorbed in the NO_x absorbent 47.
So long as the oxygen concentration in the exhaust gas is
high, NO_2 is produced on the surface of the platinum Pt
46. So long as the NO_x absorbing capability of the NO_x
35 absorbent 47 is not saturated, the NO_2 is absorbed in the
NO_x absorbent 47 and nitrate ions NO_3^- are produced.

As opposed to this, by making the air-fuel ratio in

the combustion chamber 2 rich or the stoichiometric air-fuel ratio or feeding a reducing agent from the reducing agent feed valve 13 to make the air-fuel ratio of the exhaust gas rich or the stoichiometric air-fuel ratio,

5 since the oxygen concentration in the exhaust gas falls, the reaction proceeds in the reverse direction ($NO_3^- \rightarrow NO_2$) and therefore the nitrate ions NO_3^- in the NO_x absorbent 47 are released from the NO_x absorbent 47 in the form of NO_2. Next, the released NO_x is reduced by the

10 unburned HC or CO included in the exhaust gas.

In this way, when the air-fuel ratio of the exhaust gas is lean, that is, when burning fuel under a lean air-fuel ratio, the NO_x in the exhaust gas is absorbed in the NO_x absorbent 47. However, if continuing to burn fuel

15 under a lean air-fuel ratio, during that time the NO_x absorbing capability of the NO_x absorbent 47 will end up becoming saturated and therefore NO_x will end up no longer being able to be absorbed by the NO_x absorbent 47. Therefore, in this embodiment, as shown in FIG. 23,

20 before the absorbing capability of the NO_x absorbent 47 becomes saturated, a reducing agent is supplied from the reducing agent feed valve 14 so as to temporarily make the air-fuel ratio of the exhaust gas rich and thereby release the NO_x from the NO_x absorbent 47.

25 However, platinum Pt 46 inherently has activity at a low temperature. However, the basicity of the NO_x absorbent 47 is considerably strong. Therefore, the activity of the platinum Pt 46 at a low temperature, that is, the oxidation ability, ends up being weakened. As a

30 result, if the temperature TC of the NO_x storing catalyst 11 falls, the NO oxidation action weakens and the NO_x purification rate falls. The solid line of FIG. 24 shows the relationship between the NO_x purification rate due to the exhaust purification catalyst 11, which is the same

35 as the value shown in FIG. 4, and the temperature TC of the exhaust purification catalyst 11, while the broken line of FIG. 24 shows the relationship between the NO_x

purification rate by the NO_x storing catalyst 29 and the temperature TC of the NO_x storing catalyst 29. In this embodiment, as will be understood from FIG. 24, when the temperature TC of the NO_x storing catalyst 29 becomes

5   lower than about 250°C, the NO_x purification rate rapidly falls.

On the other hand, exhaust gas contains SO_2. This SO_2 is oxidized at the platinum Pt 46 and becomes SO_3. Next, this SO_2 is absorbed in the NO_x absorbent 47 and bonds

10   with the barium oxide BaO while diffusing in the NO_x absorbent 47 in the form of sulfate ions SO_4^{2-} to produce the stable sulfate $BaSO_4$. However, the NO_x absorbent 47 has a strong basicity, so this sulfate $BaSO_4$ is stable and hard to break down. If just making the air-fuel ratio of

15   the exhaust gas rich, the sulfate $BaSO_4$ will remain without being broken down. Therefore, in the NO_x absorbent 47, the sulfate $BaSO_4$ will increase along with the elapse of time and therefore the amount of NO_x which the NO_x absorbent 47 can absorb will fall along with the elapse

20   of time.

However, if raising the temperature of the NO_x storing catalyst 29 to 600°C or more and in that state making the air-fuel ratio of the exhaust gas rich, SO_x will be released from the NO_x absorbent 47. Therefore, in

25   this embodiment, when the amount of SO_x absorbed in the NO_x absorbent 47 increases, the temperature of the NO_x storing catalyst 29 is raised up to 600°C or more and the air-fuel ratio of the exhaust gas is made rich.

As will be understood from the above explanation, in

30   this embodiment, an exhaust purification catalyst 11 using a carrier 50 having base points on its surface and having a precious metal catalyst 51 carried dispersed on the surface of the carrier 50 without forming a layer of a NO_x absorbent able to absorb NO_x under a lean air-fuel

35   ratio and a NO_x storing catalyst 29 forming on the surface of a carrier 45 a layer of a NO_x absorbent 47 able to

absorb NO_x under a lean air-fuel ratio and having a
precious metal catalyst 46 carried dispersed on the
surface are arranged in series in the engine exhaust
passage. When the NO_x in the exhaust gas is mainly being
purified by the NO_x purification catalyst 11, the air-fuel
ratio of the exhaust gas flowing into the exhaust
purification catalyst 11 is temporarily switched from
lean to rich before the entire surface of the precious
metal catalyst 51 carried on the surface of the carrier
50 of the NO_x purification catalyst 11 suffers from oxygen
poisoning. When the NO_x in the exhaust gas is mainly being
purified by the NO_x storing catalyst 29, the air-fuel
ratio of the exhaust gas flowing into the NO_x storing
catalyst 29 is temporarily switched from lean to rich
before the NO_x storing capacity of the NO_x storing
catalyst 29 becomes saturated.

Note that in this case, as will be understood from
FIG. 24, when the temperature of the NO_x purification
catalyst 11 is in a first temperature region lower than a
set temperature Ts, the NO_x in the exhaust gas is mainly
purified by the exhaust purification catalyst 11, while
when the temperature of the NO_x storing catalyst 29 is in
the second temperature region at the higher temperature
side from the first temperature region, that is, higher
than the set temperature Ts, the NO_x in the exhaust gas is
mainly purified by the NO_x storing catalyst 29. In the
example shown in FIG. 24, the set temperature Ts is about
250°C.

Further, as the temperature TC of the catalyst at
FIG. 24, a representative temperature representing the
temperature of the exhaust purification catalyst 11 and
the temperature of the NO_x storing catalyst 29 is used. As
this representative temperature TC, the temperature of
the NO_x storing catalyst 29 or the temperature of the
exhaust purification catalyst 11 detected by the
temperature sensor 20 or the temperature of the exhaust
gas detected by the temperature sensor 49 is used. In

this case, when the representative temperature TC is lower than the predetermined set temperature Ts, for example, 250°C, it is judged that the temperature of the exhaust purification catalyst 11 is in the first

5   temperature region, while when the representative temperature TC is higher than the predetermined set temperature TS, for example 250°C, it is judged that the temperature of the NO_x storing catalyst 29 is in the second region.

10   Next, the processing of the NO_x and SO_x will be explained.

        In this embodiment as well, when NO_x is mainly purified in the NO_x purification catalyst 11, the amount of oxygen poisoning of the precious metal catalyst of the

15   exhaust purification catalyst 11, for example, platinum Pt 51, is calculated using the map shown in FIG. 5C. When the calculated amount of oxygen poisoning exceeds a predetermined allowable value, the air-fuel ratio of the exhaust gas is switched from lean to rich and thereby the

20   oxygen poisoning of the platinum Pt 51 is eliminated.

        FIG. 25 shows the time chart of the control for elimination of oxygen poisoning and the control for release of SO_x. The control shown in FIG. 25 is substantially the same as the control shown in FIG. 6.

25   That is, as shown in FIG. 25, every time the cumulative value ΣW of the amount W of oxygen poisoning exceeds an allowable value WX, the reducing agent is supplied from the reducing agent feed valve 13 and the air-fuel ratio A/F of the exhaust gas flowing into the NO_x purification

30   catalyst 11 is temporarily switched from lean to rich. At this time, the oxygen poisoning of the platinum 51 is eliminated and the NO_x adsorbed or held on the catalyst carrier 50 is released from the catalyst carrier 50 and reduced.

35   On the other hand, the cumulative value $\Sigma SOX1$ of the amount of SO_x held at the exhaust purification catalyst 11

is also calculated. When the cumulative value $\Sigma SOX1$ of this amount of SO_x exceeds an allowable value SX1, the action of release of the SO_x from the NO_x purification catalyst 11 is performed. That is, first, the methods shown in (II) to (IV) of FIG. 7 are used to raise the temperature TC of the NO_x purification catalyst 11 until the SO_x release temperature TX1 is reached. This SO_x release temperature TX1, as explained above, is about 500°C when no additive 52 is added to the catalyst carrier 51. When an additive 52 is added to the catalyst carrier 51, it is a temperature between about 500°C to 550°C corresponding to the amount of addition of the additive 52.

If the temperature TC of the exhaust purification catalyst 11 reaches the SO_x release temperature TX1, the air-fuel ratio of the exhaust gas flowing into the exhaust purification catalyst 11 is switched from lean to rich and the release of SO_x from the exhaust purification catalyst 11 is started. While the SO_x is being released, the temperature TC of the exhaust purification catalyst 11 is held at the SO_x release temperature TX1 or more and the air-fuel ratio of the exhaust gas is held rich. Next, when the SO_x release action ends, the action of raising the temperature of the exhaust purification catalyst 11 is stopped and the air-fuel ratio of the exhaust gas is returned to lean.

Further, in this embodiment, when the NO_x is mainly purified by the NO_x storing catalyst 29, the amount of NO_x absorbed in the NO_x absorbent 47 of the NO_x storing catalyst 29 is calculated. When the calculated amount of NO_x absorbed exceeds a predetermined allowable value, the air-fuel ratio of the exhaust gas is switched from lean to rich, whereby the NO_x is made to be released from the NO_x absorbent 47.

The amount of NO_x exhausted from the engine per unit time is a function of the fuel injection amount Q and the

engine speed N. Therefore, the amount NOXA of NO_x absorbed in the NO_x absorbent 47 per unit time becomes a function of the fuel injection amount Q and the engine speed N. In this embodiment, the amount NOXA of NO_x absorbed per unit time corresponding to the fuel injection amount Q and the engine speed N is found in advance by experiments. This amount NOXA of NO_x absorbed is stored in advance in the ROM 32 in the form of a map as shown by FIG. 26A as a function of the fuel injection amount Q and engine speed N.

On the other hand, FIG. 26B shows the relationship between the NO_x absorption rate KN to the NO_x absorbent 47 and the temperature TC of the NO_x storing catalyst 29. This NO_x absorption rate KN has the same tendency as the NO_x absorption rate shown by the broken line of FIG. 24 with respect to the temperature TC of the NO_x storing catalyst 29. The actual amount of NO_x absorbed in the NO_x absorbent 45 is shown by the product of NOXA and KN.

FIG. 27 shows a time chart of the control for release of NO_x and SO_x. As shown in FIG. 27, every time the cumulative value ΣNOX of the amount $NOXA \cdot KN$ of NO_x absorbed exceeds an allowable value NX, a reducing agent is supplied from the reducing agent feed valve 13 and the air-fuel ratio A/F of the exhaust gas flowing into the NO_x storing catalyst 29 is temporarily switched from lean to rich. At this time, NO_x is released from the NO_x absorbent 47 and reduced.

On the other hand, the $\Sigma SOX2$ of the amount of SO_x absorbed in the NO_x absorbent 47 is also calculated. When the cumulative value $\Sigma SOX2$ of this amount of SO_x exceeds an allowable value SX2, the action of release of the SO_x from the NO_x absorbent 47 is performed. That is, first, the methods shown in (II) to (IV) of FIG. 7 are used to raise the temperature TC of the NO_x storing catalyst 29 until the SO_x release temperature TX2 is reached. This SO_x release temperature TX2 is 600°C or more.

If the temperature TC of the NO_x storing catalyst 29 reaches the SO_x release temperature TX2, the air-fuel ratio of the exhaust gas flowing into the NO_x storing catalyst 29 is switched from lean to rich and the release of SO_x from the NO_x absorbent 47 is started. While the SO_x is being released, the temperature TC of the NO_x storing catalyst 29 is held at the SO_x release temperature TX2 or more and the air-fuel ratio of the exhaust gas is held rich. Next, when the SO_x release action ends, the action of raising the temperature of the NO_x storing catalyst is stopped and the air-fuel ratio of the exhaust gas is returned to lean.

Note that the t_0 shown in FIG. 27 and the t_0 shown in FIG. 25 express the same time. Therefore, the rich interval when getting the NO_x released from the NO_x absorbent 47 and the rich time when getting the SO_x released from the NO_x absorbent 45 are longer than the rich interval for eliminating oxygen poisoning at the exhaust purification catalyst 11 and the rich time for releasing the SO_x.

FIG. 28 shows the routine for control for feeding a reducing agent from the reducing agent feed valve 13. This routine is executed by interruption every predetermined time interval.

Referring to FIG. 28, first, at step 600, it is judged if a representative temperature TC representing the temperature of the NO_x storing catalyst 29 and the exhaust purification catalyst is lower than a set temperature Ts, for example, 250°C. When TC<Ts, the routine proceeds to step 601, where the amount W of oxygen poisoning per unit time is calculated from the map shown in FIG. 5(C). Next, at step 602, the amount W of oxygen poisoning W is added to ΣW so as to calculate the cumulative value ΣW of the amount of oxygen poisoning. Next, at step 603, it is judged if the cumulative value ΣW of the amount of oxygen poisoning has exceeded an

allowable value WX, that is, if the state is a little
before the entire surface of the platinum 51 suffers from
oxygen poisoning. When $\Sigma W \leq WX$, the routine jumps to step
605. As opposed to this, when $\Sigma W > WX$, the routine proceeds

5   to step 604, where the poisoning elimination processing
is performed, then the routine proceeds to step 605.
       At step 605, the value $k1 \cdot Q$ of a constant $k1$
multiplied with the fuel injection amount Q is added to
$\Sigma SOX1$. This $\Sigma SOX1$ expresses the cumulative value of the

10   amount of SO_x held on the exhaust purification catalyst
11. Next, at step 606, it is judged if the cumulative
value $\Sigma SOX1$ of the amount of SO_x has exceeded an allowable
value SX1. When $\Sigma SOX1 \leq SX1$, the processing cycle is ended,
while when $\Sigma SOX1 > SX1$, the routine proceeds to step 607,

15   where the SO_x release processing I is performed.
       On the other hand, when it is judged at step 600
that $TC \geq Ts$, the routine proceeds to step 608, where the
amount NOXA of NO_x absorbed per unit time is calculated
from the map shown in FIG. 26A, and the NO_x absorption

20   rate KN shown in FIG. 26B is calculated. Next, at step
609, by adding the actual amount $KN \cdot NOXA$ of NO_x absorbed
to ΣNOX, the cumulative value ΣNOX of the amount of NO_x
absorbed is calculated. Next, at step 610, it is judged
if the cumulative value ΣNOX of the amount of NO_x absorbed

25   has exceeded an allowable value NX. When $\Sigma NOX \leq NX$, the
routine jumps to step 612. As opposed to this, when
$\Sigma NOX > NX$, the routine proceeds to step 611, where the NO_x
release processing is performed, then the routine
proceeds to step 612.

30   At step 612, the value $k2 \cdot Q$ of the constant $k2$
multiplied with the fuel injection amount Q is added to
$\Sigma SOX2$. This $\Sigma SOX2$ shows the cumulative value of the
amount of SO_x absorbed in the NO_x absorbent 47. Next, at
step 613, it is judged if the cumulative value $\Sigma SOX2$ of

35   the amount of SO_x has exceeded an allowable value SX2.

When $\Sigma SOX2 \leq SX2$, the processing cycle is ended. When $\Sigma SOX2 > SX2$, the routine proceeds to step 614, where the SO_x release processing II is performed.

FIG. 29 shows the routine for processing for elimination of poisoning executed at step 604 of FIG. 28.

Referring to FIG. 29, first, at step 620, the amount of feed of the reducing agent required for making the air-fuel ratio of the exhaust gas a rich air-fuel ratio of for example about 13 is calculated. Next, at step 621, the feed time of the reducing agent is calculated. This reducing agent feed time is normally 10 seconds or less. Next, at step 622, the feed of the reducing agent from the reducing agent feed valve 13 is started. Next, at step 623, it is judged if the feed time of the reducing agent calculated at step 621 has elapsed. When the feed time of the reducing agent has not elapsed, the routine returns to step 623 again. At this time, the feed of the reducing agent is continued and the air-fuel ratio of the exhaust gas is maintained at the rich air-fuel ratio of about 13. As opposed to this, when the feed time of the reducing agent has elapsed, that is, when the oxygen poisoning of the platinum 51 has been eliminated, the routine proceeds to step 624, where the feed of the reducing agent is stopped, then the routine proceeds to step 625, where the ΣW is cleared. Next, the routine proceeds to step 605 of FIG. 28.

FIG. 30 shows the routine for processing of the SO_x release processing I executed at step 607 of FIG. 28.

Referring to FIG. 30, first, at step 630, control is performed for raising the temperature of the exhaust purification catalyst 11. That is, the fuel injection pattern from the fuel injector 3 is changed to an injection pattern of any of (II) to (IV) of FIG. 7. If the fuel injection pattern is changed to any injection pattern of (II) to (IV) of FIG. 7, the exhaust gas temperature rises and therefore the temperature of the

exhaust purification catalyst 11 rises. Next, the routine proceeds to step 631, where it is judged if the representative temperature TC representing the temperature of the exhaust purification catalyst 11 has reached the SO_x release temperature TX1 or more. When TC<TX1, the routine returns to step 631 again. As opposed to this, when TC≥TX1, the routine proceeds to step 632, where the amount of feed of the reducing agent required for making the air-fuel ratio of the exhaust gas a rich air-fuel ratio of about 14 is calculated. Next, at step 633, the feed time of the reducing agent is calculated. The feed time of the reducing agent is several minutes. Next, at step 634, the feed of the reducing agent from the reducing agent feed valve 13 is started. Next, at step 635, it is judged if the feed time of the reducing agent calculated at step 633 has elapsed. When the feed time of the reducing agent has not elapsed, the routine returns to step 635. At this time, the feed of the reducing agent is continued and the air-fuel ratio of the exhaust gas is maintained at the rich air-fuel ratio of about 14. As opposed to this, when the feed time of the reducing agent has elapsed, that is, when the release of the SO_x held in the exhaust purification catalyst 11 has been completed, the routine proceeds to step 636, where the feed of the reducing agent is stopped. Next, at step 637, the action of raising the temperature of the exhaust purification catalyst 11 is stopped, then the routine proceeds to step 638, where the $\Sigma SOX1$ and ΣW are cleared.

FIG. 31 shows the routine for processing for release of NO_x executed at step 611 of FIG. 28.

Referring to FIG. 31, first, at step 640, the amount of feed of the reducing agent required for making the air-fuel ratio of the exhaust gas a rich air-fuel ratio of for example about 13 is calculated. Next, at step 641, the feed time of the reducing agent is calculated. This reducing agent feed time is normally 10 seconds or less. Next, at step 642, the feed of the reducing agent from

the reducing agent feed valve 13 is started. Next, at step 643, it is judged if the feed time of the reducing agent calculated at step 641 has elapsed. When the feed time of the reducing agent has not elapsed, the routine returns to step 643. At this time, the feed of the reducing agent is continued and the air-fuel ratio of the exhaust gas is maintained at the rich air-fuel ratio of about 13. As opposed to this, when the feed time of the reducing agent has elapsed, that is, when the action of release of NO_x from the NO_x absorbent 47 has been completed, the routine proceeds to step 644, where the feed of the reducing agent is stopped, then the routine proceeds to step 645, where the ΣNOX is cleared. Next, the routine proceeds to step 612 of FIG. 28.

FIG. 32 shows the routine for processing of the SO_x release processing II executed at step 614 of FIG. 28.

Referring to FIG. 32, first, at step 650, control is performed for raising the temperature of the NO_x storing catalyst 29. That is, the fuel injection pattern from the fuel injector 3 is changed to an injection pattern of any of (II) to (IV) of FIG. 7. If the fuel injection pattern is changed to any injection pattern of (II) to (IV) of FIG. 7, the exhaust gas temperature rises and therefore the temperature of the NO_x storing catalyst 29 rises. Next, the routine proceeds to step 651, where it is judged if a representative temperature TC representing the temperature of the NO_x storing catalyst 29 has reached the SO_x release temperature TX2 or more. When TC<TX2, the routine returns to step 651. As opposed to this, when TC≥TX2, the routine proceeds to step 652, where the feed amount of the reducing agent required for making the air-fuel ratio of the exhaust gas a rich air-fuel ratio of about 14 is calculated. Next, at step 653, the feed time of the reducing agent is calculated. The feed time of the reducing agent is around 10 minutes. Next, at step 654, the feed of the reducing agent from the reducing agent feed valve 13 is started. Next, at step 655, it is judged

if the feed time of the reducing agent calculated at step
653 has elapsed. When the feed time of the reducing agent
has not elapsed, the routine returns to step 655. At this
time, the feed of the reducing agent is continued and the
air-fuel ratio of the exhaust gas is maintained at the
rich air-fuel ratio of about 14. As opposed to this, when
the feed time of the reducing agent has elapsed, that is,
when the release of the SO_x held in the NO_x absorbent 47
has been completed, the routine proceeds to step 656,
where the feed of the reducing agent is stopped. Next, at
step 657, the action of raising the temperature of the NO_x
storing catalyst 29 is stopped, then the routine proceeds
to step 658, where the $\Sigma SOX2$ and ΣNOX are cleared.

FIG. 33 shows still another embodiment. In this
embodiment, as the sensor 22 arranged in the exhaust pipe
21, a NO_x concentration sensor which can detect the
concentration of NO_x in the exhaust gas is used. This NO_x
concentration sensor 22 generates an output voltage V
proportional to the NO_x concentration. In the exhaust
purification catalyst 11, if the oxygen poisoning of the
platinum Pt 51 proceeds, the NO_x purification rate
gradually falls and as a result the concentration of NO_x
in the exhaust gas gradually increases. Therefore, in
this embodiment, when the amount of oxygen poisoning
estimated from the concentration of NO_x in the exhaust gas
has exceeded a predetermined allowable value, that is,
when the output voltage V of the NO_x concentration sensor
has exceeded the set value VX1, the air-fuel ratio of the
exhaust gas is switched from lean to rich.

Further, with the NO_x storing catalyst 29, as the
amount of NO_x absorbed of the NO_x absorbent 47 approaches
saturation, the NO_x purification rate gradually falls and
as a result the concentration of NO_x in the exhaust gas
gradually increases. Therefore, the amount of NO_x absorbed
in the NO_x absorbent 47 can be estimated from the
concentration of NO_x in the exhaust gas. In this
embodiment, when the amount of NO_x absorbed estimated from

the concentration of NO_x in the exhaust gas exceeds a predetermined allowable value, that is, when the output voltage V of the NO_x concentration sensor 22 has exceeded a set value VX2, the air-fuel ratio of the exhaust gas is switched from lean to rich.

FIG. 33 shows the routine for control for feeding a reducing agent from the reducing agent feed valve 13 in this embodiment. This routine is executed every predetermined time interval.

Referring to FIG. 33, first, at step 700, it is judged if a representative temperature TC representing the temperature of the NO_x storing catalyst 29 and the exhaust purification catalyst 11 is lower than a set temperature Ts, for example, 250°C. When TC<Ts, the routine returns to step 701 where it is judged if the output voltage V of the NO_x concentration sensor 22 has exceeded a set value VX1. When V≤VX1, the routine jumps to step 703. As opposed to this, when V>VX1, the routine proceeds to step 702, where the routine for processing for elimination of poisoning is executed, then the routine proceeds to step 703.

At step 703, the value k1·Q of the constant k1 multiplied with the fuel injection amount Q is added to $\Sigma SOX1$. This $\Sigma SOX1$ expresses the cumulative value of the amount of SO_x held on the exhaust purification catalyst 11. Next, at step 704, it is judged if the cumulative value $\Sigma SOX1$ of the amount of SO_x has exceeded an allowable value SX1. When $\Sigma SOX1 \leq SX1$, the processing cycle is ended, while when $\Sigma SOX1 > SX1$, the routine proceeds to step 705, where the SO_x release processing I shown in FIG. 30 is performed.

On the other hand, when it is judged at step 700 that TC≥Ts, the routine proceeds to step 706, where it is judged if the output voltage V of the NO_x concentration sensor 22 has exceeded a set value VX2. When V≤VX2, the routine jumps to step 708. As opposed to this, when

V>VX2, the routine proceeds to step 707, where the NO_x release processing shown in FIG. 31 is executed. Next, the routine proceeds to step 708.

At step 708, the value $k2 \cdot Q$ of the constant k2 multiplied with the fuel injection amount Q is added to $\Sigma SOX2$. This $\Sigma SOX2$ expresses the cumulative value of the amount of SO_x held in the NO_x absorbent 47. Next, at step 709, it is judged if the cumulative value $\Sigma SOX2$ of the amount of SO_x has exceeded an allowable value SX2. When $\Sigma SOX2 \leq SX2$, the processing cycle is ended, while when $\Sigma SOX2 > SX2$, the routine proceeds to step 710, where the SO_x release processing II shown in FIG. 32 is performed.

FIG. 34 and FIG. 35 show still another embodiment. In this embodiment, as the sensor 22 arranged in the exhaust pipe 21, the air-fuel ratio sensor for detecting the air-fuel ratio of the exhaust gas is used. As shown in FIG. 13, when the air-fuel ratio(A/F)out of the exhaust gas flowing out from the exhaust purification catalyst 11 becomes rich after the air-fuel ratio(A/F)in of the exhaust gas flowing into the exhaust purification catalyst 11 is switched from lean to rich, it is judged that the oxygen poisoning of platinum Pt 51 has been eliminated. At this time, the air-fuel ratio of the exhaust gas is switched from rich to lean.

Further, in this embodiment, when the air-fuel ratio of the exhaust gas for releasing the NO_x from the NO_x absorbent 47 of the NO_x storing catalyst 29 is made rich, it is judged if the action of release of NO_x from the NO_x absorbent 47 has been completed from the change of the output of the air-fuel ratio sensor 22. When it is judged that the action of release of NO_x from the NO_x absorbent 47 has been completed, the air-fuel ratio of the exhaust gas is switched from rich to lean.

Specifically speaking, in this case as well, as shown in FIG. 13, when the air-fuel ratio(A/F)in of the exhaust gas flowing into the NO_x storing catalyst 29 is

switched from lean to rich, that is, when the reducing agent is supplied from the reducing agent feed valve 13, the reducing agent, that is, the hydrocarbon, is used for reducing the NO_x released from the NO_x absorbent 47. While the NO_x is continuing to be released from the NO_x absorbent 47, the air-fuel ratio(A/F)out of the exhaust gas flowing out from the NO_x storing catalyst 29 is maintained at substantially the stoichiometric air-fuel ratio or somewhat lean. Next, when NO_x is no longer released from the NO_x absorbent 47, the hydrocarbons pass through the NO_x storing catalyst 29, so the air-fuel ratio(A/F)out of the exhaust gas flowing out from the NO_x storing catalyst 29 becomes rich. Therefore, when the air-fuel ratio(A/F)out of the exhaust gas flowing out from the NO_x storing catalyst 29 becomes rich after the air-fuel ratio(A/F)in of the exhaust gas flowing into the NO_x storing catalyst 29 is switched from lean to rich, it can be judged that the action of release of NO_x from the NO_x absorbent 47 has been completed.

The control for feeding the reducing agent in this embodiment is performed using the routine shown in FIG. 28. However, the processing for elimination of poisoning at step 604 in FIG. 28 uses the routine shown in FIG. 34, while the processing for release of NO_x at step 611 of FIG. 28 uses the routine shown in FIG. 35.

Referring to the routine for processing for elimination of poisoning shown in FIG. 34, first, at step 800, the amount of the reducing agent required for making the air-fuel ratio of the exhaust gas a rich air-fuel ratio of for example about 13 is calculated. Next, the routine proceeds to step 801, where the feed of the reducing agent from the reducing agent feed valve 13 is started. Next, at step 802, it is judged if the air-fuel ratio(A/F)out of the exhaust gas detected by the air-fuel ratio sensor 22 has become rich. When the air-fuel ratio(A/F)out is not rich, the routine returns to step 802. As opposed to this, when the air-fuel ratio(A/F)out

is rich, that is, when the oxygen poisoning of the platinum 41 has been eliminated, the routine proceeds to step 803, where the feed of the reducing agent is stopped, then the routine proceeds to step 804, where the ΣW is cleared. Next, the routine proceeds to step 605 of FIG. 28.

On the other hand, referring to the NO_x release processing routine shown in FIG. 35, first, at step 810, the amount of the reducing agent required for making the air-fuel ratio of the exhaust gas a rich air-fuel ratio of for example about 13 is calculated. Next, the routine proceeds to step 811, where the feed of the reducing agent from the reducing agent feed valve 13 is started. Next, at step 812, it is judged if the air-fuel ratio(A/F)out of the exhaust gas detected by the air-fuel ratio sensor 22 has become rich. When the air-fuel ratio(A/F)out is not rich, the routine returns to step 812. As opposed to this, when the air-fuel ratio(A/F)out is rich, that is, when the action of release of NO_x from the NO_x absorbent 47 has been completed, the routine proceeds to step 813, where the feed of the reducing agent is stopped, then the routine proceeds to step 814, where the ΣNOX is cleared. Next, the routine proceeds to step 612 of FIG. 28.

FIG. 36 and FIG. 37 show a further embodiment of the present invention.

As shown in FIG. 36, in this embodiment as well, like in the embodiment shown in FIG. 21, a NO_x storing catalyst 29 is arranged at the upstream side of the engine exhaust passage, while an exhaust purification catalyst 11 is arranged at the downstream side of the engine exhaust passage. However, in this embodiment, an acidic catalyst 70 such as an oxidation catalyst is arranged at the upstream side of the NO_x storing catalyst 29. Further, FIG. 36 shows the change of the temperature of the exhaust gas when performing control for raising the temperature to get the SO_x released from the NO_x

storing catalyst 29 or the exhaust purification catalyst 11 and the strengths of the basicities of the catalysts 70, 29, and 11, that is, the basicity degrees.

As explained above, the basicity of the NO_x absorbent 47 of the NO_x storing catalyst 29 is considerably strong, while the basicity of the exhaust purification catalyst 11 is weak. In other words, the basicity degree of the NO_x storing catalyst 29 is considerably higher than the basicity degree of the exhaust purification catalyst 11. In this case, as explained above, if the basicity degree of the catalyst becomes higher, the holding force of the SO_x becomes stronger along with this. If the holding force of the SO_x becomes stronger, the SO_x will no longer be easily released even if raising the temperature of the catalyst. That is, as shown in FIG. 37, the SO_x release temperature becomes higher as the basicity degree of the catalyst becomes higher.

On the other hand, the temperature of the exhaust gas at the time of control for raising the temperature for releasing the SO_x becomes higher at a catalyst positioned at the upstream side than a catalyst positioned at the downstream side. Therefore, if seen from the viewpoint of releasing the SO_x, it is preferable to arrange the catalyst with a high NO_x release temperature, that is, the catalyst with a high basicity degree, at the upstream side. That is, seen from the viewpoint of the release of SO_x, it can be said to be preferable to raise the basicity degree the higher the catalyst bed temperature at the time of control for raising the temperature. In the embodiment shown in FIG. 21 and FIG. 36, if seen from this viewpoint, the order of arrangement of the exhaust purification catalyst 11 and the NO_x storing catalyst 29 is determined by the strengths of the basicities of the catalysts. The catalyst with a strong basicity, that is, the NO_x storing catalyst 29, is arranged upstream of the catalyst with a weak basicity, that is, the NO_x purification catalyst 11.

Note that the temperature raising action of the exhaust gas due to the heat of the oxidation reaction of the unburned HC in the exhaust gas is the most powerful. Therefore, in the embodiment shown in FIG. 36, the acidic catalyst 70 is arranged at the upstream side of the NO_x storing catalyst 29.

Note that each of the NO_x storing catalysts 29 shown in FIG. 21 and FIG. 36 may also be comprised of a particulate filter shown in FIG. 15A and FIG. 15B.

In this way, when configuring the NO_x storing catalyst 29 by a particulate filter, the peripheral walls of the exhaust gas inflow passages 60 and exhaust gas outflow passages 61, that is, the surfaces of the two sides of the partitions 64 and inside walls of the fine holes of the partitions 64 are formed on them with a layer of a catalyst carrier comprised of alumina. As shown in FIG. 22, this catalyst carrier 45 carries a precious metal catalyst 46 and NO_x absorbent 47 on it. Note that in this case as well, platinum Pt is used as the precious metal catalyst. In this way, even when configuring the NO_x storing catalyst 29 by a particulate filter, when the air-fuel ratio of the exhaust gas is lean, the NO_x absorbent 47 absorbs the NO_x and the SO_x. Therefore, in this case as well, the control for release of the NO_x and SO_x similar to the control for release of the NO_x and SO_x for the NO_x storing catalyst 29 is performed.

Further, when configuring the NO_x storing catalyst 29 by a particulate filter, the particulate contained in the exhaust gas is trapped in the particulate filter and the trapped particulate is successively made to burn by the heat of the exhaust gas. If a large amount of particulate deposits on the particulate filter, the injection pattern is switched to any one of the injection patterns (II) to (IV) of FIG. 7 or a reducing agent is supplied from the reducing agent feed valve 13 and thereby the exhaust gas temperature is made to rise. Due to this, the deposited

particulate is ignited and burned.

FIG. 38 to FIG. 41 show various examples of arrangement of the NO_x storing catalyst 29 and the exhaust purification catalyst 11.

In the example shown in FIG. 38, the exhaust purification catalyst 11 is arranged at the upstream side of the NO_x storing catalyst 29. In this case, even when the temperature of the exhaust gas is low, the exhaust purification catalyst 11 can purify the NO_x. Further, when the exhaust gas is lean, the exhaust purification catalyst 11 converts part of the NO contained in the exhaust gas to NO_2. This NO_2 is easily stored in the NO_x storing catalyst 29. On the other hand, when feeding a reducing agent from the reducing agent feed valve 13 to make the air-fuel ratio of the exhaust gas rich, this reducing agent is changed to a low molecular weight hydrocarbon in the exhaust purification catalyst 11. Therefore, it is possible to reduce the NO_x released from the NO_x absorbent 47 of the NO_x storing catalyst 29 well.

On the other hand, in the example shown in FIG. 38, the NO_x storing catalyst 29 may also be comprised of a particulate filter. In this case, the NO_2 produced in the exhaust purification catalyst 11 promotes the oxidation of the particulate deposited on the particulate filter ($NO_2+C\rightarrow CO_2+N_2$).

In the example shown in FIG. 39, exhaust purification catalysts 11 are arranged upstream and downstream of the NO_x storing catalyst 29. In this case, the NO_x storing catalyst 29 may be formed from a particulate filter.

In the example shown in FIG. 40, an exhaust purification catalyst 11 is arranged downstream of the NO_x storing catalyst 29 and a monolithic catalyst 71 is arranged upstream of the NO_x storing catalyst 29. The upstream half of the monolithic catalyst 71 is comprised of the exhaust purification catalyst 11, while the downstream half is comprised of the NO_x storing catalyst

29. In this example as well, the NO_x storing catalyst 29 may be formed from a particulate filter.

In the example shown in FIG. 41, a monolithic catalyst 72 is arranged in the engine exhaust passage.

5   The center part of this monolithic catalyst 72 is comprised of the NO_x storing catalyst 29, while the upstream part and downstream part are comprised of exhaust purification catalysts 11. In this example as well, the NO_x storing catalyst 29 may be formed from a

10 particulate filter.

Next, a low temperature combustion method suitable for raising the temperature of the exhaust purification catalyst 11 etc. and making the air-fuel ratio of the exhaust gas rich will be explained.

15 In the compression ignition type internal combustion engine shown in FIG. 1 etc., if increasing the EGR rate (amount of EGR gas/(amount of EGR gas+amount of intake air)), the amount of production of smoke will gradually increase and then peak. If further increasing the EGR

20 rate, the amount of production of smoke will then rapidly drop. This will be explained while referring to FIG. 42 showing the relationship between the EGR rate and the smoke when changing the degree of cooling of the EGR rate. Note that in FIG. 42, the curve A shows the case of

25 powerfully cooling the EGR gas to maintain the temperature of the EGR gas at about 90°C, the curve B shows the case of using a small cooling device to cool the EGR gas, and the curve C shows the case of forcibly cooling the EGR gas.

30 As shown by the curve A of FIG. 42, when powerfully cooling the EGR gas, the amount of production of smoke peaks when the EGR rate becomes a little lower than 50 percent. In this case, if making the EGR rate about 55 percent or more, almost no smoke will be produced any

35 longer. On the other hand, as shown by the curve B of FIG. 42, when slightly cooling the EGR gas, the amount of production of smoke will peak at an EGR rate slightly

higher than 50 percent. In this case, if making the EGR
rate about 65 percent or more, almost no smoke will be
produced any longer. Further, as shown by the curve C of
FIG. 42, when not forcibly cooling the EGR gas, the

5   amount of production of smoke peaks at an EGR rate of
near 55 percent. In this case, if making the EGR rate
about 70 percent or more, almost no smoke will be
produced any more.

     Smoke is no longer produced if making the EGR gas

10   rate 55 percent or more in this way because the
temperature of the fuel and its surrounding gas at the
time of combustion does not become that high due to the
heat absorbing action of the EGR gas, that is, low
temperature combustion is performed, and as a result the

15   hydrocarbons will not grow to soot.

     This low temperature combustion has the feature of
enabling the amount of production of NO_x to be reduced
while suppressing the production of smoke regardless of
the air-fuel ratio. That is, if the air-fuel ratio is

20   made rich, the fuel becomes in excess, but the combustion
temperature is suppressed at a low temperature, so the
excess fuel will not grow into soot and therefore no
smoke will be generated. Further, at this time, only a
very small amount of NO_x will be generated. On the other

25   hand, even when the average air-fuel ratio is lean or
when the air-fuel ratio is the stoichiometric air-fuel
ratio, if the combustion temperature becomes high, a
small amount of soot will be produced, but in low
temperature combustion, the combustion temperature is

30   suppressed to a low temperature, so no smoke at all will
be produced and only a very small amount of NO_x will be
produced either.

     On the other hand, during this low temperature
combustion, the temperature of the fuel and its

35   surrounding gas becomes lower, but the temperature of the
exhaust gas rises. This will be explained with reference
to FIG. 43A and FIG. 43B.

The solid line of FIG. 43A shows the relationship between the average gas temperature Tg in the combustion chamber 5 and the crank angle at the time of low temperature combustion, while the broken line of FIG. 43A shows the relationship between the average gas temperature Tg in the combustion chamber 5 and the crank angle at the time of normal combustion. Further, the solid line of FIG. 43B shows the relationship between the temperature Tf of the fuel and its surrounding gas and the crank angle at the time of low temperature combustion, while the broken line of FIG. 43B shows the relationship between the temperature Tf of the fuel and its surrounding gas and the crank angle at the time of normal combustion.

During low temperature combustion, the amount of EGR is greater than during normal combustion. Therefore, as shown in FIG. 43A, before compression top dead center, that is, during the compression stroke, the average gas temperature Tg at the time of low temperature combustion shown by the solid line becomes higher than the average gas temperature Tg at the time of normal combustion shown by the broken line. Note that at this time, as shown FIG. 43B, the temperature Tf of the fuel and its surrounding gas becomes substantially the same temperature as the average gas temperature Tg.

Next, the fuel starts to be burned near compression top dead center, but in this case, when low temperature combustion is performed, as shown by the solid line of FIG. 43B, the temperature Tf of the fuel and its surrounding gas does not become that much higher due to the heat absorbing action of the EGR gas. As opposed to this, during normal combustion, there is a large amount of oxygen around the fuel, so as shown by the broken line in FIG. 43B, the temperature Tf of the fuel and its surrounding gas becomes extremely high. In this way, during normal combustion, the temperature Tf of the fuel and its surrounding gas becomes considerably higher than

the case of low temperature combustion, but temperature
of the other gas, which accounts for the majority of the
gas, becomes lower at the time of normal combustion
compared with low temperature combustion. Therefore, as
shown in FIG. 43A, the average gas temperature Tg in a
combustion chamber 2 near compression top dead center
becomes higher during low temperature combustion than
normal combustion. As a result, as shown in FIG. 43A, the
temperature of the burnt gas in the combustion chamber 2
after the combustion has been completed becomes higher
during low temperature combustion than normal combustion.
Consequently, if performing low temperature combustion,
the temperature of the exhaust gas becomes higher.

However, if the required torque TQ of the engine
becomes high, that is, if the fuel injection amount
becomes greater, the temperature of the fuel and the
surrounding gas at the time of the combustion becomes
higher, so low temperature combustion becomes difficult.
That is, low temperature combustion is only possible at
the time of engine medium and low load operation where
the amount of heat generated due to combustion is
relatively small. In FIG. 44, the region I shows the
operating region where first combustion where the amount
of inert gas of the combustion chamber 5 is larger than
the amount of inert gas where the amount of generation of
soot peaks, that is, low temperature combustion, can be
performed, while the region II shows the operating region
where only second combustion where the amount of inert
gas in the combustion chamber is smaller than the amount
of inert gas where the amount of generation of soot
peaks, that is, normal combustion is possible.

FIG. 45 shows the target air-fuel ratio A/F in the
case of low temperature combustion in the operating
region I, while FIG. 46 shows the opening degree of the
throttle valve 9, the opening degree of the EGR control
valve 15, the EGR rate, the air-fuel ratio, the injection
start timing θS, the injection end timing θE, and the

injection amount in accordance with the required torque TQ in the case of low temperature combustion in the operating region I. Note that FIG. 46 also shows the opening degree of the throttle valve 9 at the time of normal combustion performed in the operating region II.

From FIG. 45 and FIG. 46, it is learned that at the time of low temperature combustion in the operating region I, the EGR rate is made 55 percent or more and the air-fuel ratio A/F is made a lean air-fuel ratio of 15.5 to 18 or so. Note that as explained above, at the time of low temperature combustion in the operating region I, even if the air-fuel ratio is made rich, almost no smoke is generated.

In this way, at the time of low temperature combustion, it is possible to make the air-fuel ratio rich without causing almost any generation of smoke. Therefore, when the air-fuel ratio of the exhaust gas should be made rich to eliminate oxygen poisoning or release SO_x, it is possible to perform low temperature combustion and make the air-fuel ratio rich under low temperature combustion.

Further, as explained above, if performing low temperature combustion, the exhaust gas temperature rises. Therefore, to release SO_x or make the deposited particulate ignite and burn, it is also possible to perform the low temperature combustion when the exhaust gas temperature should be raised.

As explained above, according to the present invention, a high NO_x purification rate can be obtained.
